

Comparisons were made between algorithm 2.1 - 2.6 for FloatType 64 vs FloatType 32 for an $m=n=k$ matrix. I found that a larger error occurred when the FloatType was 32, this is caused by the loss of magnitude when lowering the float type. A second observation is there are higher GFLOPs/s for the loop orderings 2.5-2.6, there is no comparison in the error so it cannot be determined whether this is optimized.
